The present invention generally relates to structured filaments having improved fire resistance. More specifically, the invention relates to the use of triazine polymers in a polyamide formulation to improve fire resistance. A wide variety of polymeric materials can burn and release combustion products and other by-products of combustion into the surrounding atmosphere. These by-products can create an extreme atmosphere that is hazardous to health and property. Protective clothing is normally worn by workers and protectors to protect them from the hazards of these combustion by-products. Unfortunately, this protective clothing is made from fabrics that are flammable and/or form toxic gases when burned. When the protective clothing is used as a part of a fire prevention system, the wearer or firefighter suffers the additional heat and inhalation of smoke and toxic gases that are released into the surrounding atmosphere, and the toxic fumes and heat pose a greater threat to the safety of the firefighter or other individuals on the scene. Therefore, there is a need for a protective material that does not burn or release toxic fumes or heat, and that is also not flammable. In addition, the protective material should be relatively inexpensive and easy to manufacture, and should protect the wearer from burn injury during fires. In general, it is an object of the present invention to provide a protective material that does not burn or release toxic fumes or heat, and that is also not flammable. In addition, the protective material should be relatively inexpensive and easy to manufacture, and should protect the wearer from burn injury during fires. These and other objects will be apparent to those skilled in the art. The present invention is directed to a controlled impedance electrical connector, and more particularly to a connector which is designed to provide relatively high performance while maintaining relatively low cost. Controlled impedance connectors for high performance applications and, in particular, for high speed military type connectors have been developed in the past. These connectors have relatively low performance but very low cost. The development of the present connector has been a joint development between the Armed Forces Staff College and several private sector firms. A controlled impedance connector is used as a module to form a modular connector assembly. The problems with previous controlled impedance connectors include a high cost. For example, some connector designs cost approximately \$400,000 per connector. The design philosophy of the present connector is to eliminate hand soldering and simplify the mechanical structure. This is accomplished by forming a molded connector base which incorporates both mechanical and electrical features in a single unit. This molded connector base is then connected to a

The present invention relates to an apparatus for manufacturing and purifying tobacco, more particularly to a tobacco purification apparatus having improved control of humidity during the smoking process. The state of art of tobacco purification apparatus is shown in U.S. Pat. No. 3,612,011, in which tobacco is fed from a hopper to a rotary filter in a cylindrical chamber with perforated sides, having two ventilation openings at the top and one at the bottom. The space between the side walls is filled with a drying agent that can be ventilated in a similar manner. Tobacco in the filter rests on a conveyor, and a fan is provided below the chamber so that air passes upwardly through the cigarettes and tobacco and then drops down through the drying agent in the space between the side walls. Fresh air is then drawn into the space through the ventilation openings at the top of the chamber, out through the fan below the chamber and into the exhaust. Ventilation is essential to the proper functioning of the apparatus and the drying agent. Another apparatus for the purification of tobacco by drying, disclosed in German patent publication No. 1,804,569, consists of a rotating cylinder or drum having a horizontal axis. The space inside the drum is filled with a drying agent that can be ventilated by means of a fan, which also draws in fresh air. The rotation of the drum is driven by a motor, which is started by a foot pedal, and the discharged air is fed back into the drum through a circulation duct. The dried tobacco can be removed by opening a door, and the drum can then be emptied. Apparatus of the type disclosed in the German publication operates relatively well. However, a relatively large amount of tobacco is removed from the drum at each drying operation. Moreover, control of the drying is difficult because the drum is not contained in a self-enclosed housing and moisture must be exchanged with the ambient air. There is also disclosed in German patent publication Nos. 2,844,924 and 1,790,089, an apparatus for drying tobacco in a housing. Drying agent is introduced into the housing through a supply conduit that can be closed by a valve. The dried tobacco is removed from the housing through an opening at the bottom of the housing. A motor driving a fan is provided inside the housing, and fresh air is drawn in by the fan and expelled through the exhaust. Due to the continuous circulation of air inside the housing, control of the drying is
